

React Foundations

(**Jsx, class vs className, static vs dynamic websites, State, components, re-rendering**)

Why do we need React??

For most static websites(which doesn't change its content (html doesn't change) once written) we don't need much.

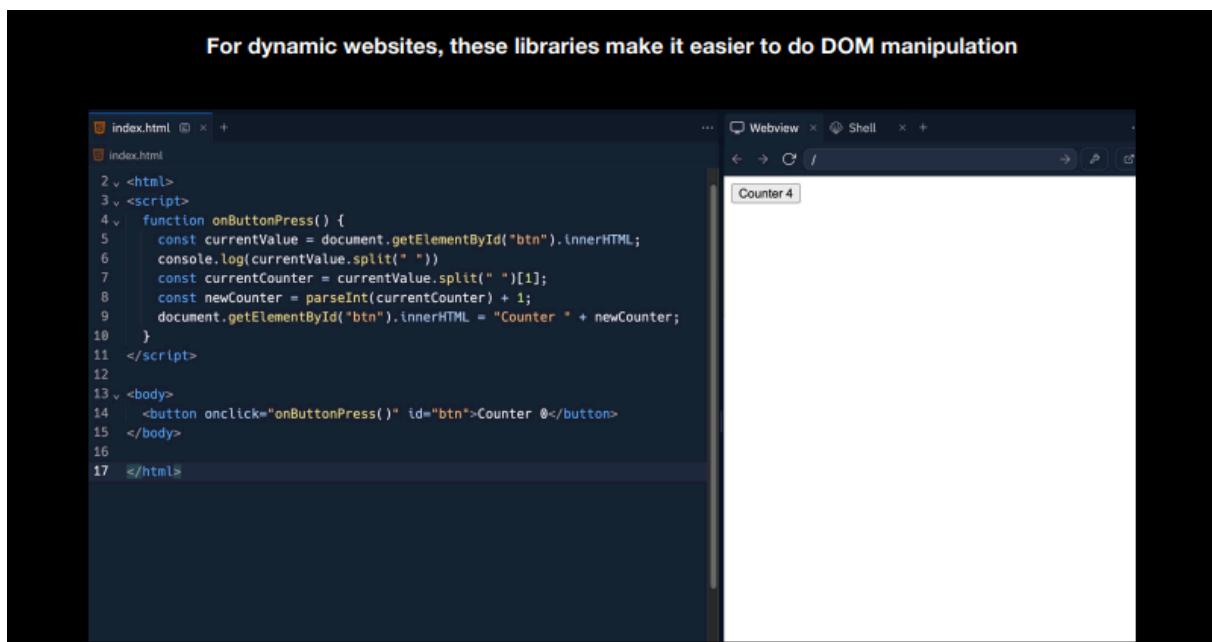

The screenshot shows a code editor with a dark theme. On the left is a sidebar with various icons. The main area displays the following HTML code:

```
ReactFoundations > index.html > html
1  <!DOCTYPE html>
2  <html lang="en">
3  <head>
4      <meta charset="UTF-8">
5      <meta name="viewport" content="width=device-width,
6          initial-scale=1.0">
7      <title>Document</title>
8  </head>
9  <body>
10     <h1>Lorem ipsum dolor sit amet.</h1>
11     <h3>Lorem ipsum dolor sit amet consectetur adipisicing elit. Pariatur id numquam doloribus tempora laboriosam minima fugit eos laudantium nemo accusamus.</h3>
12     <h2>Lorem, ipsum dolor sit amet consectetur adipisicing elit.</h2>
13     <p>Lorem ipsum dolor sit amet consectetur adipisicing elit. Asperiores dolores cum excepturi odit quis voluptatibus.</p>
14  </body>
15 </html>
```

Even dynamic websites can be written in raw html css and javascript.

For dynamic websites, these libraries make it easier to do DOM manipulation.

The screenshot shows a code editor with a dark theme. On the left is a sidebar with various icons. The main area displays the following HTML and JavaScript code:

```
index.html > index.html > Webview > Shell
For dynamic websites, these libraries make it easier to do DOM manipulation

index.html
1 <html>
2 <script>
3 function onButtonPress() {
4     const currentValue = document.getElementById("btn").innerHTML;
5     console.log(currentValue.split(" "))
6     const currentCounter = currentValue.split(" ")[1];
7     const newCounter = parseInt(currentCounter) + 1;
8     document.getElementById("btn").innerHTML = "Counter " + newCounter;
9 }
10 </script>
11 <body>
12     <button onclick="onButtonPress()" id="btn">Counter 0</button>
13 </body>
14 </html>
```

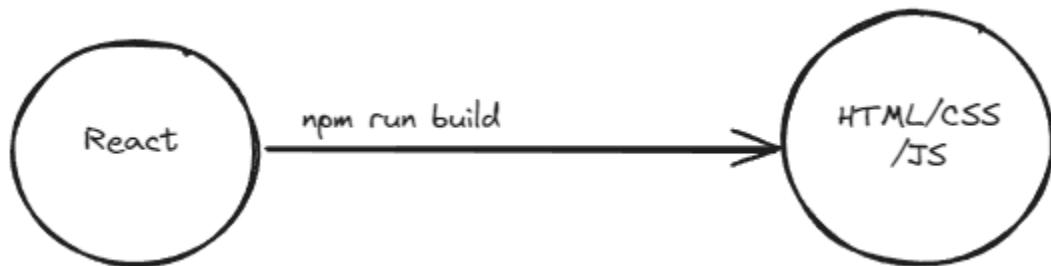

On the right, a browser window titled "Counter 4" is shown, displaying the output of the code.

split : split the string given a delimiter.

This above example written in pure js. This is medium to write

As we write applications like linkedIn which changes continuously it gets very hard to write.

React is just an easier way to write normal HTML/ CSS/ JS . It's a new syntax that under the hood gets converted into HTML/CSS/JS.

Why React??

People realised it's harder to do DOM manipulation the conventional way.

There were libraries that came into the picture that made it slightly easy, but still for a very big app it's very hard (JQuery)

Eventually, VueJS/React created a new syntax to do frontends

Under the hood , the react compiler convert your code into HTML/ CSS/ JS.

Lets see an example

Problem with this approach

1. Too much code you have to write as the developer
2. As your app scales (todo app for eg), this gets harder and harder.

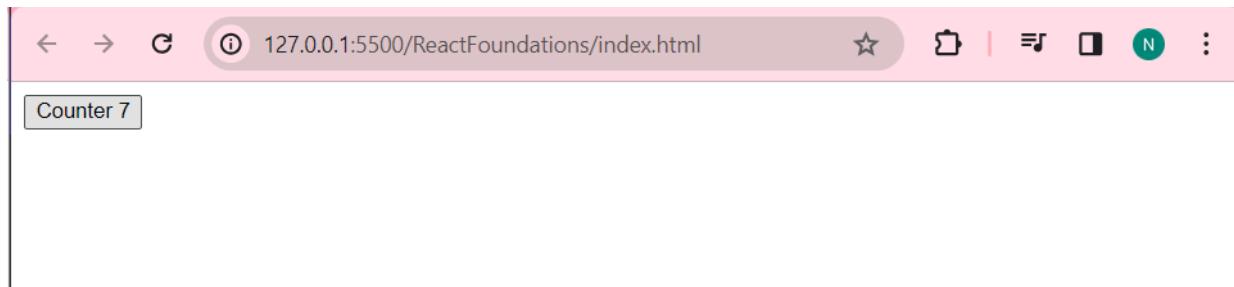

```
4 <script>
5   function onButtonPress() {
6     const currentValue = document.getElementById('btn').innerHTML;
7     const currentCounter = currentValue.split(" ")[1];
8     const newCounter = parseInt(currentCounter) + 1;
9     document.getElementById('btn').innerHTML = `Counter ${newCounter}`;
10  }
11 </script>
12
13 <body>
14   <button onclick="onButtonPress()" id="btn">Counter 0</button>
15
16
17 </body>
```

```

<!DOCTYPE html>
<html>
<script>
  function onButtonPress() {
    const currentValue = document.getElementById("btn").innerHTML;
    console.log(currentValue.split(" "))
    const currentCounter = currentValue.split(" ")[1];
    const newCounter = parseInt(currentCounter) + 1;
    document.getElementById("btn").innerHTML = "Counter " + newCounter;
  }
</script>
<!-- parsing to integer -->
<body>
  <button onclick="onButtonPress()" id="btn">Counter 0</button>
</body>

</html>

```

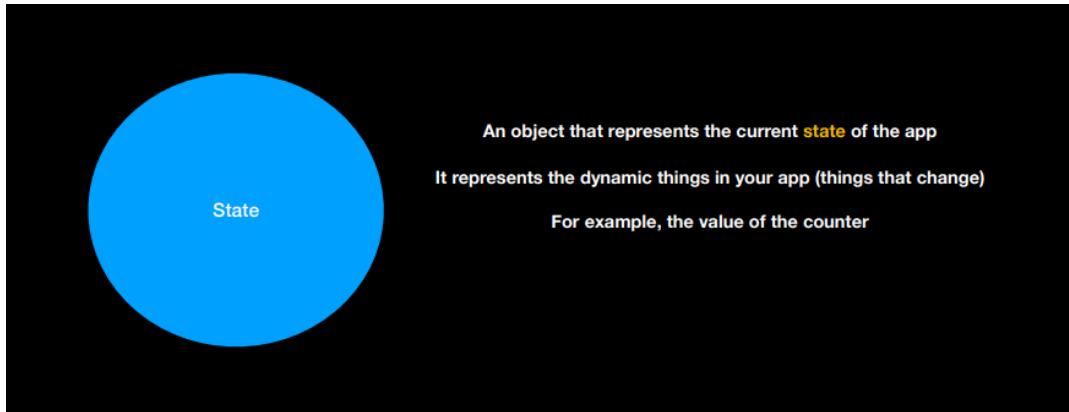

Some react jargon

When we create a react app, we need to worry about three things

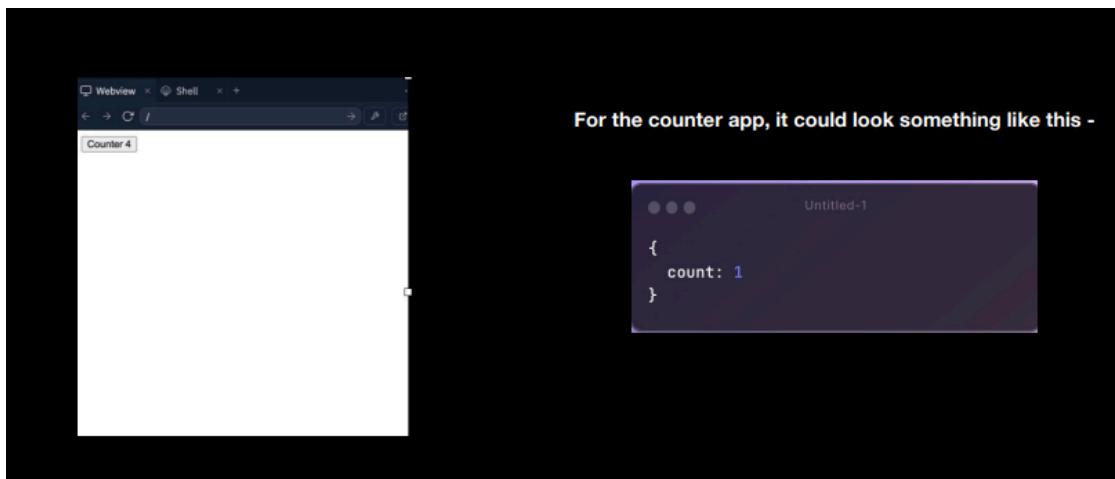

- Components
- State
- Re-rendering

Whenever we write react code we need to write State and Components code rest React handles.

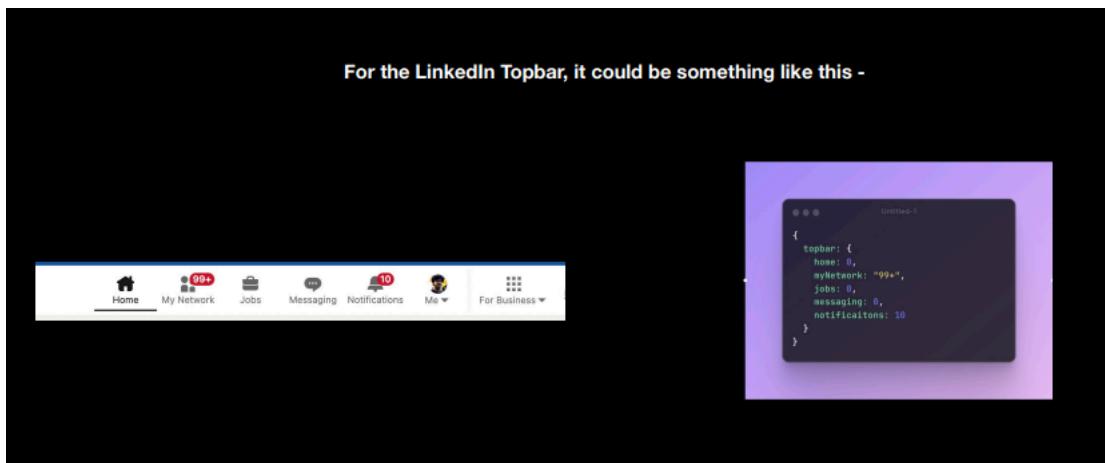

State:

State of dynamic Counter APP

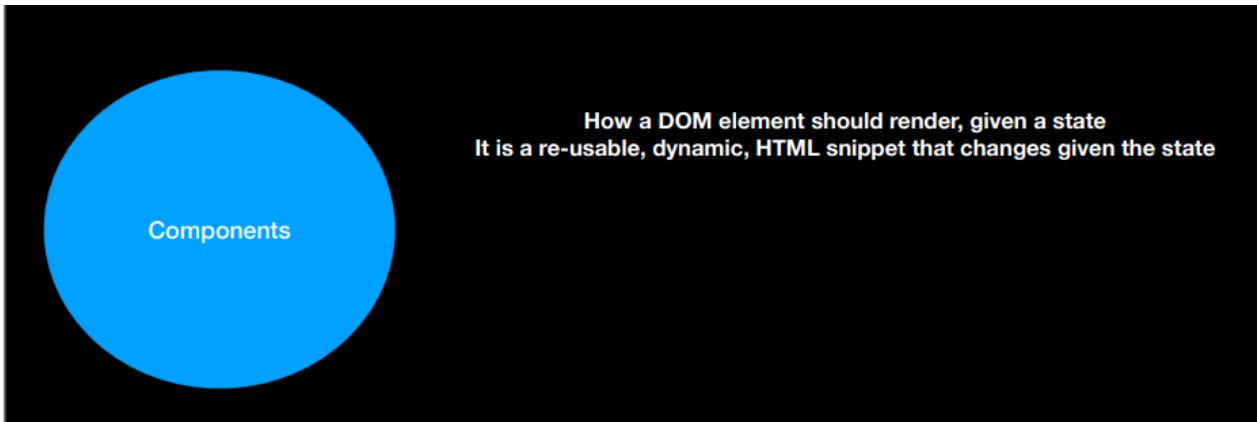

For LinkedIn Topbar

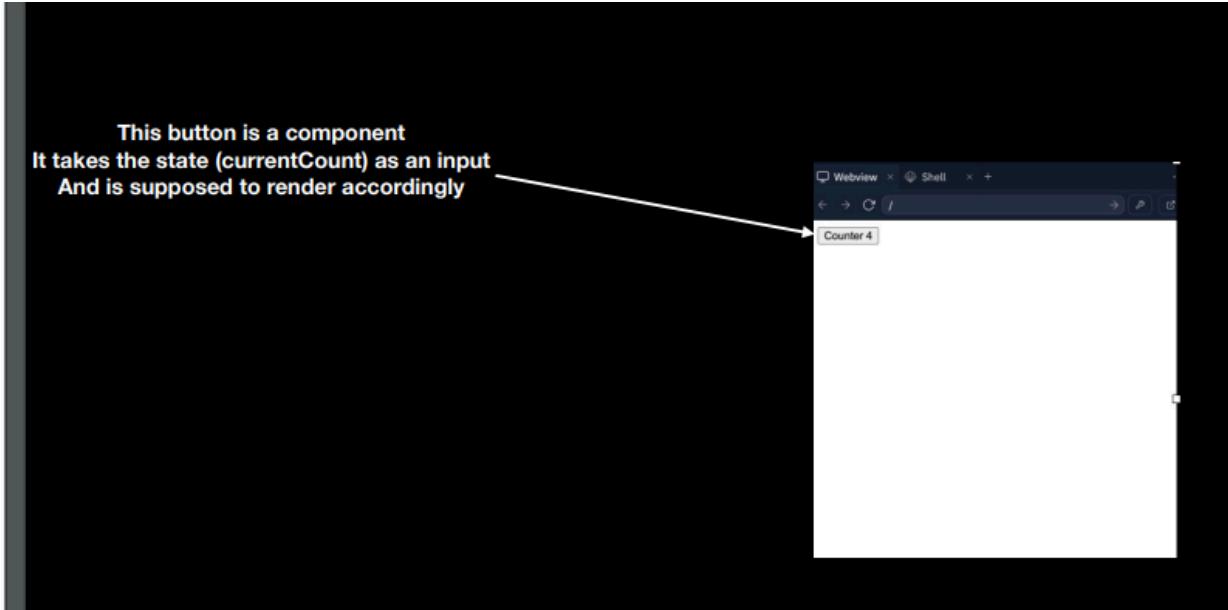

This topbar has bunch of components

Component

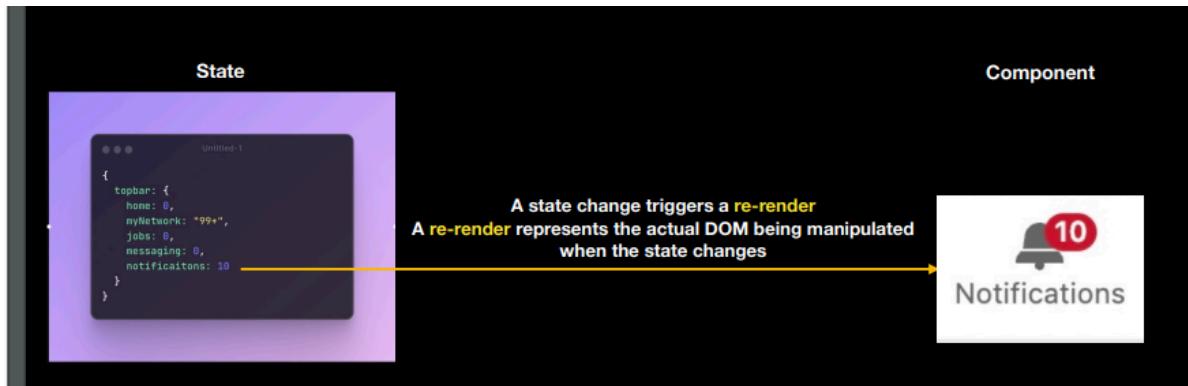

Lets see our example of Dynamic counter App

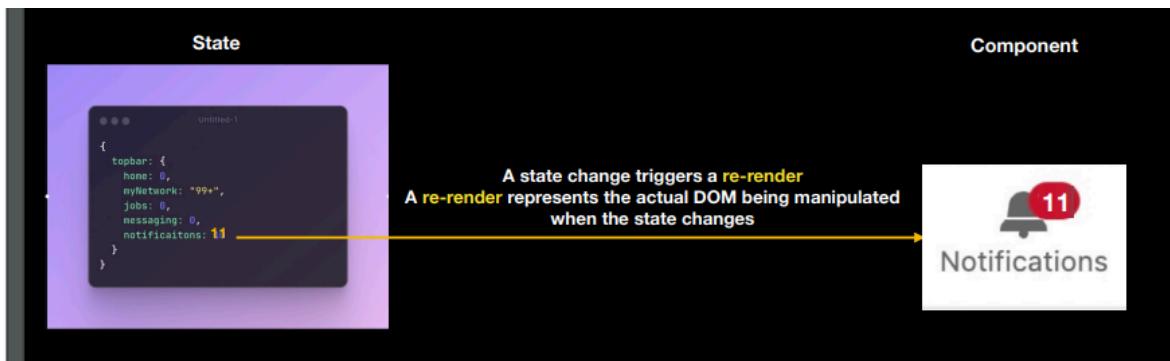

Re-Rendering

Re-rendering is the actual DOM being manipulated , when the state changes

notifications count increases to 11

We have to usually define all our components once, and then all you have to do is update the state of your app. React takes care of re-rendering your app.

Let's create a counter app using state/components (still using Javascript and DOM manipulation)

```
<!DOCTYPE html>
<html lang="en">
<head>
  <meta charset="UTF-8">
  <meta name="viewport" content="width=device-width, initial-scale=1.0">
  <title>Document</title>
</head>
<body>
  <div id="buttonParent">
  </div>
  <script>
    // state
```

```

let state = {
    count: 0
}
function onButtonPress() {
    state.count++;
    buttonComponentReRender()
}
// function define -> function define -> function define ->
functioncall (makes sure control reaches inside the
buttonComponentReRender)

// rerendering a DOM and re putting a button
function buttonComponentReRender() {
    document.getElementById("buttonParent").innerHTML = "";
// Clearing the DOM , if we dont clear the DOM more and more button will
keep on getting appended.
    const component = buttonComponent(state.count);
    // calls button component

document.getElementById("buttonParent").appendChild(component);
}

// component
function buttonComponent(count) {
    const button = document.createElement("button");
    button.innerHTML = `Counter ${count}`;
    button.setAttribute("onclick","onButtonPress()");
    return button;
}
buttonComponentReRender();
</script>
</body>
</html>

```

```

<script>
let state = {
  count: 0
};

function onButtonPress(){
  state.count++;
  buttonComponentReRender();
}

function buttonComponentReRender(){
  document.getElementById("buttonParent").
  innerHTML = "";
  const component = buttonComponent(state.count);
  document.getElementById("buttonParent").
  appendChild(component);
}

function buttonComponent(count){
  const button = document.createElement
  ("button");
  button.innerHTML = `Counter ${count}`;
  button.setAttribute("onclick","onButtonPress()");
  return button;
}

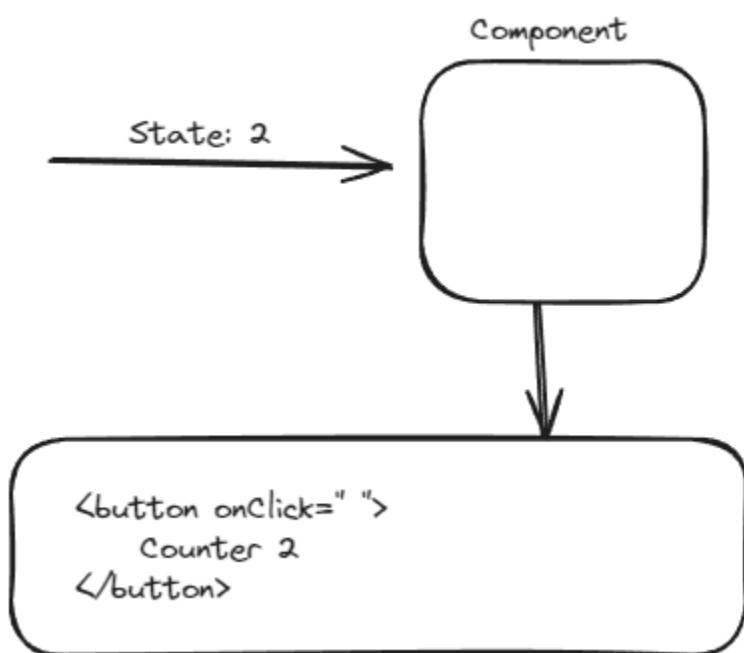

buttonComponentReRender();
</script>
</body>

```

State initialisation

Defining the button component

The react library

React under the hood works like this.

In React we define

Initial state

Component

A function which take props or state as input and return back actual HTML of something on our website it is component.

Here in the above example we are removing everything and adding , in real world React will be calculating the diff and then updating the state.

Dynamic: LinkedIn, Facebook, Insta

Global State

Of instagram

{

 name:Thapa

 feed:[

 {

 photoCount:_____

 likeCunt:_____

 Comments:{

 1:" Ham tere bin ab reh nahi skte tere bina kya vajudh mera"

 }

 }

]

}

The equivalent code in React looks like this

```
0 0 0
Untitled-1

<!DOCTYPE html>
<html>

<body>
  <div id="buttonParent">
  </div>
  <script>
    let state = {
      count: 0
    }

    function onButtonPress() {
      state.count++;
      buttonComponentReRender();
    }

    function buttonComponentReRender() {
      document.getElementById('buttonParent').innerHTML = '';
      const component = buttonComponent(state.count);
      document.getElementById('buttonParent').appendChild(component);
    }

    function buttonComponent(count) {
      const button = document.createElement("button");
      button.innerHTML = `Counter ${count}`;
      button.setAttribute("onClick", "onButtonPress()");
      return button;
    }

    buttonComponentReRender();
  </script>
</body>
</html>
```

```
'c > App.jsx ...
1 import React from 'react'
2
3 function App() {
4   const [count, setCount] = React.useState(0)
5
6   return (
7     <div>
8       | <Button count={count} setCount={setCount}></Button>
9     </div>
10  )
11}
12
13 function Button(props) {
14   function onButtonClick() {
15     props.setCount(props.count + 1);
16   }
17   return <button onClick={onButtonClick}>Counter {props.count}</button>
18 }
19
20 export default App
21 |'
```

We need to define state in certain way otherwise React wont change state.

const arr = [1,2]

arr[0] //1

const [a,b] = arr

a //1

b //2

Same as

const a = arr[0]

const b = arr[1]

Array destructuring

Object destructuring:

const { name } = {

name : "thapa",

age : 22

```
}
```

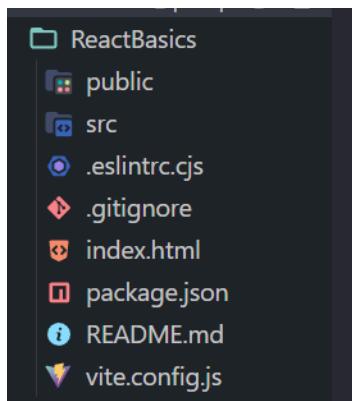

```
const [count, setCount] = React.useState(0)
```

0 is the initial state value

Lets write some React code

```
npm create vite@latest
```

This will setup basic boilerplate React application.

index.html

```
<!DOCTYPE html>
<html lang="en">
  <head>
    <meta charset="UTF-8" />
    <link rel="icon" type="image/svg+xml" href="/vite.svg" />
    <meta name="viewport" content="width=device-width, initial-scale=1.0" />
    <title>Vite + React</title>
  </head>
  <body>
    <div id="root"></div>
    <script type="module" src="/src/main.jsx"></script>
    <!-- main.jsx is a Js file . Inside which where we can write both JS and XML -->
  </body>
</html>
```

What is jsx ?

JSX stands for JavaScript XML. It is syntax extension for Javascript, most commonly used with React, a popular JavaScript library for building user interfaces. JSX allows you to write HTML-like code directly within JavaScript. This makes it easier to create and manage the user interface in React applications.

Here main.jsx is a js file, inside which we can write both JS and xml

main.jsx

```
import React from 'react'
import ReactDOM from 'react-dom/client'
import App from './App.jsx'
import './index.css'

ReactDOM.createRoot(document.getElementById('root')).render(
  <App />
)
```

Take the root element and render this Application

App.jsx

```
import './App.css'

function App() {
  return (
    <div>
      HI THERE
    </div>
  )
}

export default App
```

To run this application we do

npm install

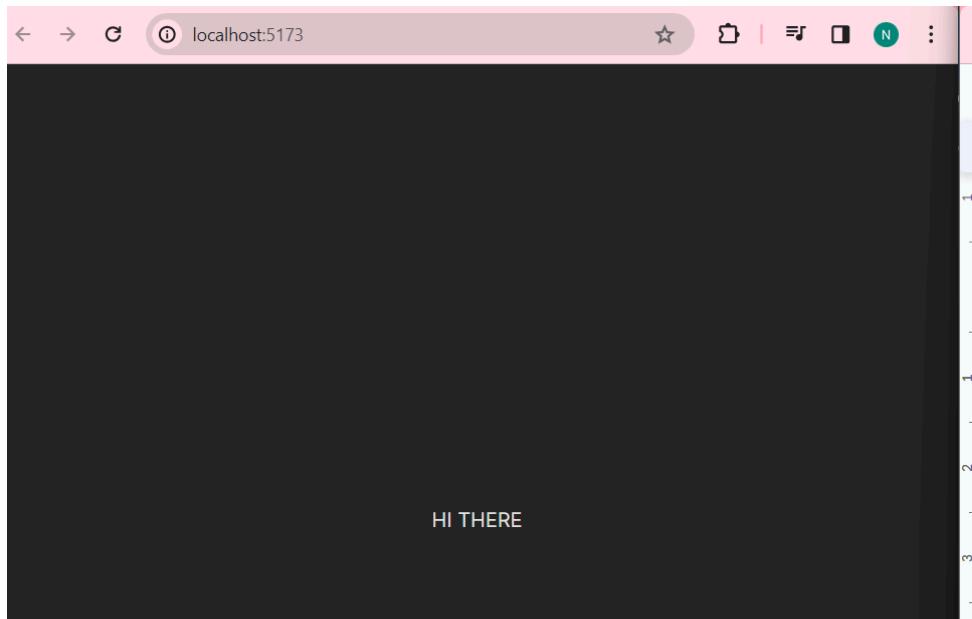

npm run dev

App.css has some css style setting

Do

npm run build to get html css js code from React code .

Now we can even delete our React code and we can host this **dist** in AWS and we will have fully functional code.

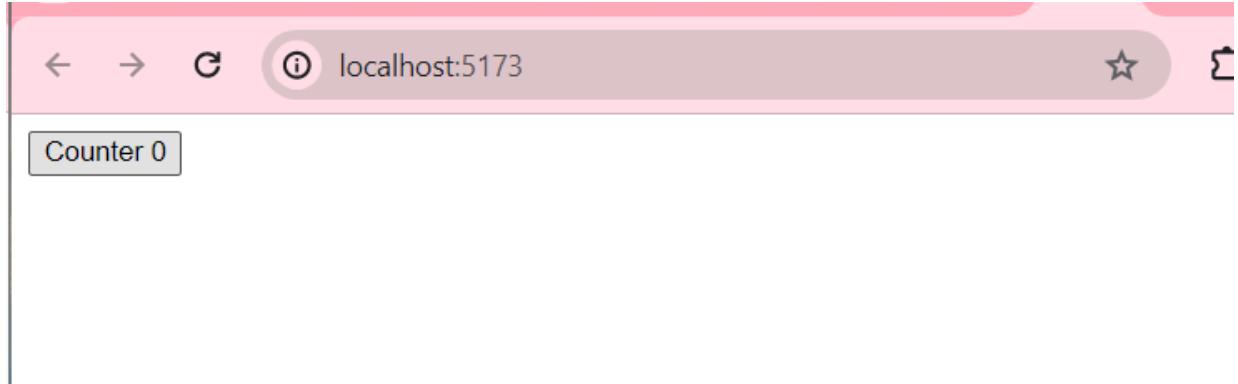

Now lets Create Our Counter App (Dynamic Website)

```
// state, components
// global state
let state = {
  count:0
}

function App () {
  return (
    <div>
      <button>Counter {state.count}</button>
    </div>
  )
}
```

```
}
```

```
export default App
```

Clicking on the Counter does nothing

```
// state, components
// global state
let state = {
  count:0
}

function App() {

  function onClickHandler() {
    state.count = state.count + 1;
    console.log(state.count);
  }

  return (
    <div>
      {/* this is XML */}
      <button onClick={onClickHandler}>Counter {state.count}</button>
    </div>
  )
}

export default App
```

Although this much of code look correct but the problem is that it doesn't work correctly.

Lets see the console

The screenshot shows a terminal window with a dark background. At the top, there is an error message in a red box: "✖ [hmr] Failed to reload /src/App.jsx. This could be due to syntax errors or importing non-existent modules. (see errors above)" followed by the file path "hmr.ts:249". Below the error message, the terminal displays the following code from App.jsx:

```
1 App.jsx:11
2 App.jsx:11
3 App.jsx:11
4 App.jsx:11
5 App.jsx:11
6 App.jsx:11
7 App.jsx:11
8 App.jsx:11
9 App.jsx:11
>
```

So state.count value is increasing then why is it not re-rendering???

Purpose of react is that we give it state and component. And anytime the state is updated the component should be re rendered.

Why isn't component re rendering?

The reason is that React doesn't see every variable as the state variable and if we want to define the state variable we have to do it certain way react understand then only DOM will be updated.

Correct Code:

```
import { useState } from "react";

function App() {
//Defining the initial state
const [count, setCount] = useState(0);
// [1,2]
// setCount is a function , it dispatch something which rerender the DOM
// Now we don't have global state variable

function onClickHandler(){
    // it has to do something like count++ but in right way , in which
state variable are updated.
```

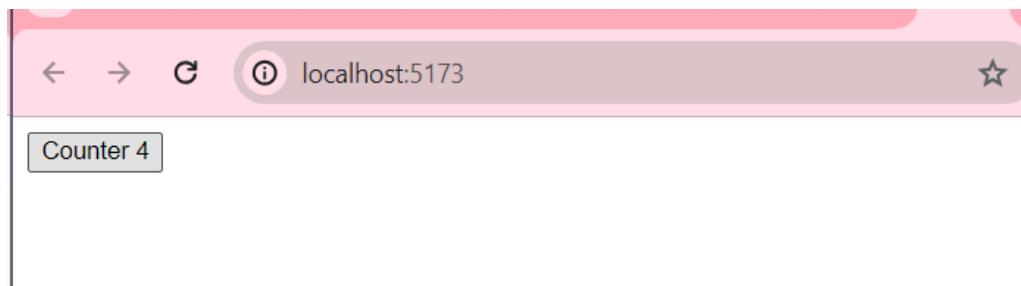

```

        setCount(count+1);
    }

    return (
        <div>
//defining dynamic html
        <button onClick={onClickHandler}>Counter {count}</button>
        </div>
    )
}

export default App

```

Lets see another better approach:

Now we can re use this component again and again

```

import { useState } from "react";
function App() {
    const [count, setCount] = useState(0);
    return (
        <div>
            <CustomButton count={count} setCount={setCount}></CustomButton>
        </div>
    )
}

// component
function CustomButton(props) {
    // buttonComponent take state as input
    // {
    //   count:
    // }
    function onClickHandler(){
        props.setCount(props.count+1);
    }
}

```

```

        }
      return <button onClick={onClickHandler}>
        Counter {props.count}
      </button>
    }
  export default App

```

Now our component is more reusable

```

function App() {
  const [count, setCount] = useState(0);
  return (
    <div>
      <CustomButton count={count} setCount={setCount}></CustomButton>
      <CustomButton count={count + 1}
setCount={setCount}></CustomButton>
      <CustomButton count={count - 1}
setCount={setCount}></CustomButton>
      <CustomButton count={count * 100}
setCount={setCount}></CustomButton>
    </div>
  )
}

```

Initially React was written as

```
return React.createElement('')
```

React was not originally written in xml way .

The equivalent code in React looks like this

Jsx syntax is a cleaner way to write components

```
App.jsx > Button
import React from 'react'

function App() {
  const [count, setCount] = React.useState(0)

  return (
    <div>
      <Button count={count} setCount={setCount}></Button>
    </div>
  )
}

function Button(props) {
  function onButtonClick() {
    props.setCount(count + 1);
  }

  return React.createElement(
    'button',
    { onClick: onButtonClick },
    `Counter ${props.count}`
  );
}

export default App
```

```
src > App.jsx ...
1 import React from 'react'
2
3 function App() {
4   const [count, setCount] = React.useState(0)
5
6   return (
7     <div>
8       <Button count={count} setCount={setCount}></Button>
9     </div>
10  )
11
12
13 function Button(props) {
14   function onButtonClick() {
15     props.setCount(props.count + 1);
16   }
17   return <button onClick={onButtonClick}>Counter {props.count}</button>
18 }
19
20 export default App
21 |
```

<https://gist.github.com/hkirat/8801c2cfad70853decd0ad1759d4e63c>

It is just syntactic sugar Both code works same way.

Now Lets make TODO APP

```
// todo application
// todo
// {
//   todos:[{title:"todo1",description:"first Todo",completed:false}]
// }
```

```
import { useState } from "react";

function App() {
  // complicated state
  const [todos, setTodos] = useState([
    {
      title:"Go to gym",
      description:"Go to gym from 7-9",
      completed: false
    }
  ]);

  return (
    <ul>
      {todos.map(todo => (
        <li key={todo.id}>
          {todo.title}
        </li>
      ))}
    </ul>
  );
}

export default App
```

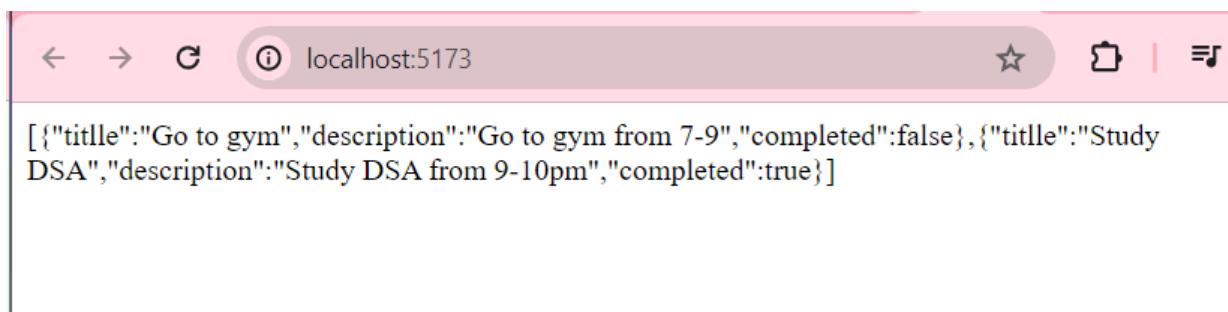

```

} , {
  title:"Study DSA",
  description:"Study DSA from 9-10pm",
  completed: true
}]);
// How do i render it one after another
return (
  <div>
    /* dumps the whole array */
    {JSON.stringify(todos)}
  </div>
)
}

export default App

```

Currently we are rendering the State variable in a not a good way.

Lets see another approach

```

import { useState } from "react";

function App() {
  // complicated state
  const [todos, setTodos] = useState([
    {
      title:"Go to gym",
      description:"Go to gym from 7-9",
      completed: false
    },
    {
      title:"Study DSA",
      description:"Study DSA from 9-10pm",
      completed: true
    }
]);

```

```

// How do i render it one after another
return (
  <div>
    <Todo title={todos[0].title}
description={todos[0].description}></Todo>
    <Todo title={todos[1].title}
description={todos[1].description}></Todo>
  </div>
)
}

// lets make a function which render a todo given,
// {
//   title,
//   description,
//   completed
// }

function Todo(props) {
  return <div>
    <h1>{props.title}</h1>
    <h2>{props.description}</h2>
  </div>
}
export default App

```

The problem with this approach is that if we add third todo then we have to add manually <Todo> tag

How can i iterate over the todos state.

```

import { useState } from "react";

function App() {
  // complicated state
  const [todos, setTodos] = useState([
    {
      title:"Go to gym",
      description:"Go to gym from 7-9",
      completed: false
    },
    {
      title:"Buy groceries",
      description:"Buy fruits and vegetables",
      completed: true
    }
  ])
  return (
    <div>
      {todos.map(todo => (
        <Todo key={todo.id} title={todo.title}
        description={todo.description} completed={todo.completed} />
      ))}
    </div>
  )
}

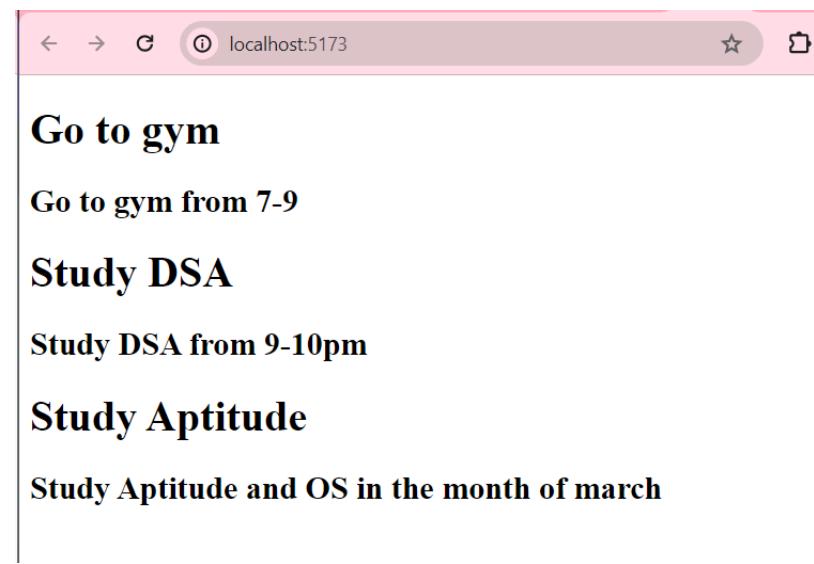

export default App

```

```

        title:"Study DSA",
        description:"Study DSA from 9-10pm",
        completed: true
    }, {
        title:"Study Aptitude",
        description:"Study Aptitude and OS in the month of march",
        completed: false
    }]);
// How do i render it one after another
return (
    <div>
        /* <Todo title={todos[0].title}
description={todos[0].description}></Todo>
<Todo title={todos[1].title}
description={todos[1].description}></Todo> */
        {todos.map(function(todo) {
            return <Todo title={todo.title}
description={todo.description}></Todo>
        })
    })
)
}

```

Lets add a button on clicking the button will add a todo

```

// this function adds a todo
function addTodo(){
  setTodos([...todos, {
    title:"new Todo",
    description:"description of new Todo"
  }])
}
return (
  <div>
    <button onClick={addTodo}>Add a random todo</button>

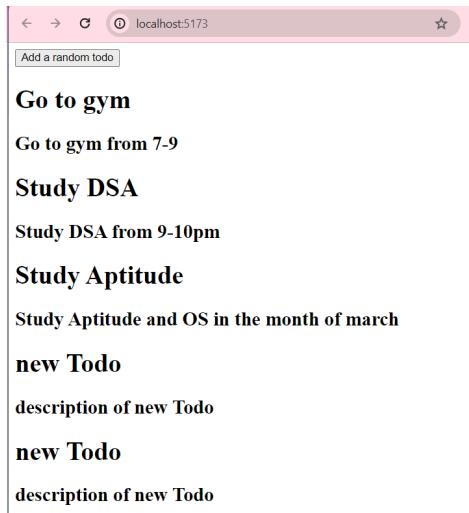

```

Suppose todos is initially [1,2]

Now if we do [...todos] it is basically [1,2]

But if we do [...todos,3] it is [1,2,3]

It basically spread the value of array

Code:

```

import { useState } from "react";

function App() {
  const [todos, setTodos] = useState([
    {
      title:"Go to gym",
      description:"Go to gym from 7-9",
    }
  ])
  return (
    <div>
      <button onClick={()=>setTodos([...todos, {
        title:"new Todo",
        description:"description of new Todo"
      }])}>Add a random todo</button>
      {todos.map(todo=><p>{todo.title} - {todo.description}</p>)}
    </div>
  )
}

export default App

```

```

        completed: false
    }, {
        title:"Study DSA",
        description:"Study DSA from 9-10pm",
        completed: true
    }, {
        title:"Study Aptitude",
        description:"Study Aptitude and OS in the month of march",
        completed: false
    }])
}

function addTodo() {
    setTodos([...todos, {
        title:"new Todo",
        description:"description of new Todo"
    }])
}
return (
    <div>
        <button onClick={addTodo}>Add a random todo</button>
        {todos.map(function(todo) {
            return <Todo title={todo.title}
description={todo.description}></Todo>
        })}
    </div>
)
}
function Todo(props) {
    return <div>
        <h1>{props.title}</h1>
        <h2>{props.description}</h2>
    </div>
}
export default App

```

Q/Na:

1. Any time a parent re-render its child re-render as well.

Even a dummy button which doesn't take any input/ state still re-renders the dummybutton.

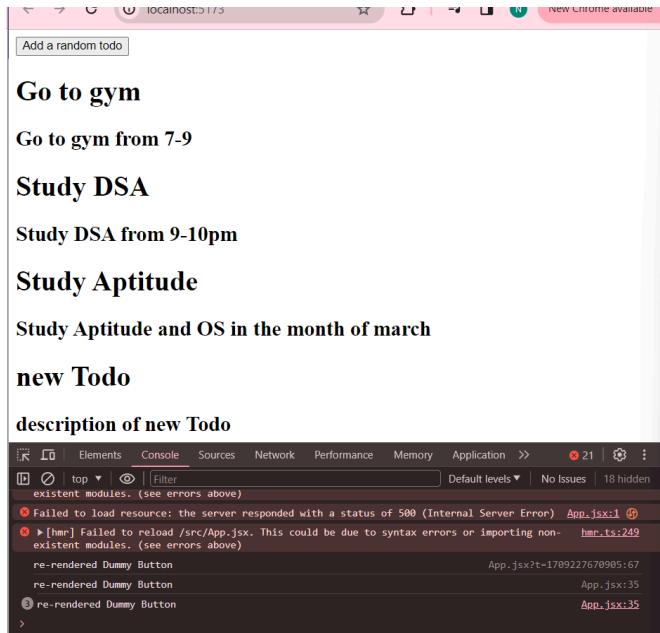

```
function App() {
  const [todos, setTodos] = useState([
    { title: "Go to gym",
      description: "Go to gym from 7-9",
      completed: false
    },
    { title: "Study DSA",
      description: "Study DSA from 9-10pm",
      completed: true
    },
    { title: "Study Aptitude",
      description: "Study Aptitude and OS in the month of march",
      completed: false
    }
  ]);

  function addTodo() {
    setTodos([...todos, {
      title: "new Todo",
      description: "description of new Todo"
    }])
  }

  return (
    <div>
      <button onClick={addTodo}>Add a random todo</button>
      {todos.map(function(todo) {
        return <Todo title={todo.title}>
          description={todo.description}</Todo>
        })}
      <DummyButton></DummyButton>
    </div>
  )
}

function DummyButton() {
  console.log("re-rendered Dummy Button")
  return <button>DSDSVF</button>
}
```

On pressing the Add a random todo , or re-rendering the parent the dummy button which doesn't even take a state variable as input still re-renders

React.memo() will prevent this

2. How does it monitor props?

```
let a=1;
window.setInterval(()=>{
  a++;
},1000)
return (
  <div>
    <DummyButton a={a}></DummyButton>
    /* this willl not result in re-rendering even if we continuously
    change the value of "a" at a set interval. Since it is not a state
    variable */
  </div>
)
```

React is not monitoring props its monitoring state only, if we pass state as a props it will re-render.

3. Adding css in React

```
<button style={{  
    border:10,  
    padding:100  
}} onClick={addTodo}>Add a random todo</button>
```

Here we are using double curly braces, outer curly braces is for specifying Js and inner curly braces are for object.

4. React context ,recoil , redux

5. State ->> useState hook

React need to watch , we need to use , useState

```
[todos, setTodos] = useState([])
```

```
Todos = [ setTodos([
```

```
])]
```

React is not watching variable, it is listening to the setTodos calls, and anytime setTodo is called with new input , it know component need to re-render, it will start the process of finding the new DOM element put it,

```
function App() {  
  const [todos, setTodos] = useState([]);  
  
  function addTodo() {  
    let newTodos = [];  
    for(let i=0; i<todos.length; i++) {  
      newTodos.push(todos[i])  
    }  
    newTodos.push({  
      title:"asda",  
      description:"asvsdafsdsd"  
    })  
    setTodos(newTodos)  
  }  
  return (  
    <div>
```

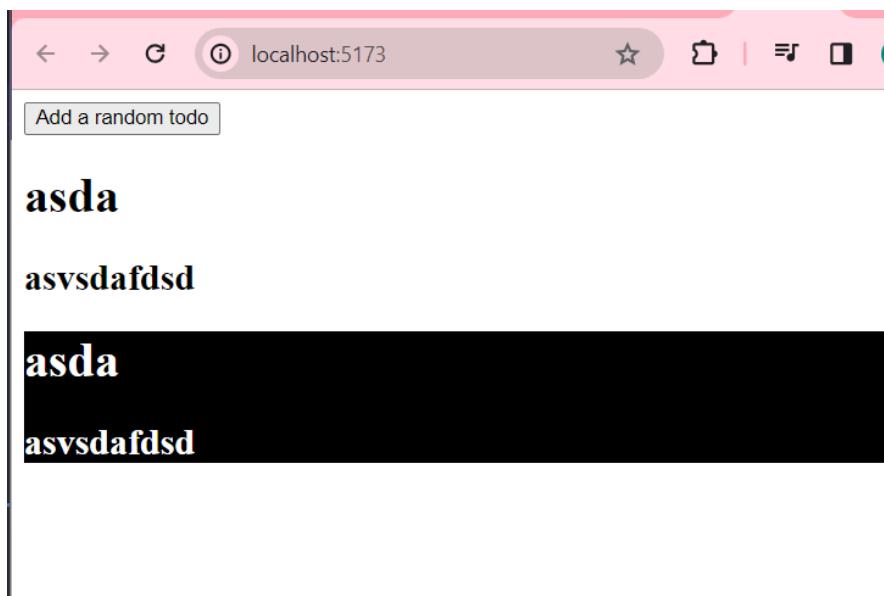

```
<button onClick={addTodo}>Add a random todo</button>
{todos.map(function(todo) {
    return <Todo title={todo.title}
description={todo.description}></Todo>
}) }
</div>
)
}
```

Child variable also need to access the global state, we pass them as props

```
<NewTodos todos={todos}></NewTodos>
<DarkNewTodos todos={todos}></DarkNewTodos>
```

We can pass state variable as props

```
function DarkNewTodos(props) {
    return <div>
{props.todos.map(function(todo) {
    return <div style={{background:"black",color:"white"} }>
<Todo title={todo.title} description={todo.description} />
</div>
}) }
</div>
}
```

Re-rendering when whenever we are adding a random todo.

6. Control flow

App got called

addTodo got called (realize Todos state is changed)

App is again called

Todo component get called

Npm run dev : used when we are developing

(hot reloading) We want to immediately show changes

npm run build : we can distribute it.

7. const [count, setCount] = useState(1);

count++;

This will generate error

Always call the setCount function if the variable is not constant dont do count++.

8. example

```
const [a, setA] = useState(0);
<Sum a={a} b={2}/>
function Sum(a, b) {
  return <div>

  </div>
}
```

At high level anytime state variable changes app will re-render.

We will learn state management library to prevent unnecessary re-renders.

9. Another example

```
const [notificationCount, NotificationComponent] = useState(0);
notificationCount = notificationCount + 2;
setCNotification();
.
```

10. Since we know that the button count will be used in button only hence we can define it in the component itself.

```
function App () {  
  const [todos, setTodos] = useState([]);  
  
  return (  
    <div>  
      <Button/>  
      <Button/>  
      <Button/>  
      <Button/>  
      <Button/>  
    </div>  
  )  
}  
  
function Button() {  
  const [count, setCount] = useState(0);  
  return <button>  
    </button>  
  // self containerd  
}
```

11. `const [todos, setTodos] = useState([]);`
 `function addTodo(){`
 `let newTodos = [...todos,{`
 `title:"acvdsas",`
 `description:"Musu musu hasai dieu malai lai"`
 `}]`
 `setTodos(newTodos);`
 `}`

{ } are only for expression not running whole for loop etc

```
ReactDOM.createRoot(document.getElementById('root')).render(  
  <App />  
)  
// All our logic is inside the root  
// Anything above and below we can't add or remove it
```

12. Why do we use props??

```
import { useState } from "react";  
  
function App() {  
  const [count, setCount] = useState(0)  
  return (  
    <div>  
  
    </div>  
  )  
}  
  
function Todo(props) {  
  return <div>  
  asdfg  
  </div>  
}  
export default App
```

Suppose we want to use state variable which is defined on App function inside the Todo function then we will use props

Const a = [1,2,3,4]

a[0] = 100;

Array is constant means its address is constant.

13. hook we have to start with use while naming it.
